Modelling and Validation of Automotive Engine Fuelled with Palm Oil Biodiesel

M. N. Azuwir, M. Z. Abdulmuin, and A. H. Adom

Abstract—This paper presents the Black-box modelling of automotive diesel engine fuelled with palm oil biodiesel (Palm Oil Methyl Ester). The aim of the work described in this paper is to obtain linear dynamic model of the palm oil biodiesel from test data. Assuming a discrete time form for the system model, an Autoregressive Moving Average with eXogenous input (ARMAX) model structures was selected in this work. A Pseudo-Random Binary Sequence (PRBS) with maximum lengths sequence of 31 has been used as the test input signal to the engine at the speed range around 2100 rpm. The input and output signals were interfaced to the plant via Matlab programming. Recursive estimation algorithm, Recursive Extended Least Squares (RELS), is used to estimate the model parameters. Finally, model validation was done by comparing the output predicted by the model against the measured output and also by error analysis. The mathematical model developed in this study present an analysis and simulation tools of engine dynamic system that forms the foundation for a systematic approach to the analysis, simulation and synthesis of the automotive palm oil biodiesel engine control systems. The model derived in this work is intended for the development of self-tuning engine speed controller in future work.

Index Terms—Identification; Modeling; Biodiesel; Palm oil biodiesel

I. INTRODUCTION

One of the key ingredients to any economic activity is energy. The energy demand in developing countries will continuously rise enormously especially in industrialized countries. By the year 2020, as inspired by the Wawasan 2020, Malaysia will become a developed country. Therefore, Malaysia needs to make sure its energy supply is adequate to accelerate its economic development. As an alternative to fossil fuel, the use of biofuel will reduce the dependency on depleting fossil fuel. The National Biofuel Policy, launched on 21 March 2006, envision that biofuel will be enhancing the nation’s prosperity and well-being by the five strategic trusts: Biofuel for transporta tion, Biofuel for industry, Biofuel for export, Biofuel for cleaner environment [1].

Studies related to alternative energy from palm waste industry in Malaysia have been rigorously done since the late 1990s. For example, Mahlia et al. [2] studied the usage of fiber and shell obtained from the processing of palm oil as fuel for the boiler. They even extend their studies toward the development of a dynamic model and simulation of the palm waste boiler [3]. While Masjuki et al [4] studied the performance and tribological characteristics of an indirect diesel engine operation on palm oil methyl esters and its emulsion.

A very comprehensive review and importance of biodiesel as transportation fuel was done by Balat and Balat [5] and Demirbas [6]. Biodiesel has demonstrated a number of promising characteristics and has become more attractive recently because of its environmental benefits. Agarwal [7] reviews the performance and emission of biodiesel in compression ignition engines, combustion analysis, wear performance on long term engine usage and economic feasibility.

Research and development efforts have demonstrated that palm oil biodiesel (palm oil methyl esters) is a good source for energy production [8],[9]. Generally, palm oil biodiesel exhibits fuel properties comparable to those of petroleum diesel, refer to Table I and Table II, and can be used directly in unmodified diesel engines.

Several studies have been done on the performance of the biofuel as a substitute fuel for unmodified diesel engine [10-14]. However, studies on biodiesel engine modeling and control are scanty. Among the foremost studies are those of Ganapathy et al. [15] who studied a methodology for thermodynamic model analysis of biodiesel engine and Ramadhas et al. [16] who developed a theoretical model and analyzed the performance characteristics of compression ignition engine fuelled by biodiesel and its blends.

System identification is the process of determining the mathematical equations that govern the model's dynamics. It consists of repeatedly selecting a model structure, computing the best model in the structure, and evaluating this model's properties to see if they are satisfactory. The process flow can be summarized as below:

i. Design an experiment for data collection – the purpose of the experiment is to collect several sets of input-output data over its entire range of operating points. The idea is to vary the input signal and observe the response of the output signal.

ii. Select and define a model structure – a model structure is a set of mathematical equations from which the final mathematical model will be derived. It could be a linear or nonlinear model.

iii. Parameter estimation – once the model has been selected a parameter estimation technique will be implemented for model fitting.

iv. Model validation – validate the mathematical model derived in the previous step.

v. Repeat the process until good model is achieved.

### A. Excitation Signal

A PRBS signal with Maximum Length Sequences (MLS) characteristics was selected as the input signal injected to the plant for identification purposes. The PRBS state can change only at discrete intervals of time, $\Delta t$ which is also known as bit interval. PRBS sequence is periodic with period, $T=N^*\Delta t$ where $N$ is sequence length. Pseudorandom binary sequence can be generated by means of a serial-input shift register with feedback using exclusive-OR gate. The signal is not truly random because the sequence repeats itself every $2^n-1$ bit intervals for an n-bit shift register. The sequence length is related to the number of registers through the following equation:

$$ N = 2^n - 1 $$ (1)

where $n$ is the number of registers.

In this experiment, the signals are generated by a computer program using the exclusive-OR and modulo-2 addition with $n = 5$. As a rule of thumb in designing the PRBS signal, the clock period $\Delta t$ is normally chosen to be approximately in the range of a fifth to a half of the output response time constant ($T_e$) i.e.

$$ \Delta t = (0.2 \text{ to } 0.5) \times T_e $$ (2)

### B. Model Structure

In this work, the system is assumed as a discrete linear model. In general, the control input $u(t)$ and the output of the system $y(t)$ can be expressed in the discrete time function form

$$ Ay(t) = Bu(t - 1) + Ce(t) $$ (3)

where $e(t)$ is the noise signal and

$$ A = 1 + a_1 z^{-1} + \ldots + a_n z^{-n} $$ (4)

$$ B = b_0 + b_1 z^{-1} + \ldots + b_m z^{-m} $$ (5)

$$ C = 1 + c_1 z^{-1} + \ldots + c_n z^{-n} $$ (6)

The polynomial coefficients of Eq.(4-6) are treated as the parameters to be determined by estimation. Thus, it is easier
to write Eq.(3) using the backshift interpretation of $z^{-1}$ and
write the equation in the form

$$y(t) = \mathbf{x}^T(t)\mathbf{\theta} + e(t)$$  \hspace{1cm} (7)

where $\mathbf{\theta}$ is the vector of unknown parameters,
$$\mathbf{\theta}^T = [-a_1, ..., -a_n, b_0, ..., b_{n_b}, c_1, ..., c_{n_c}]$$  \hspace{1cm} (8)

and $\mathbf{x}(t)$ is a regression vector consist of measured input
and output variables and also the noise terms,
$$\mathbf{x}(t) = [y(t - 1), ..., y(t - n_d), u(t - 1), ..., u(t - n_b - 1),
\phantom{+}e(t - 1), e(t - 2), ..., e(t - n_c)]$$  \hspace{1cm} (9)

The model considered in this study is the ARMAX model
which includes the noise term in the system output of Eq.
(3). In order to estimate the polynomial parameter $C$, the
value of $e(t - 1), ..., e(t - n_c)$ is required but $e(t)$ is not
measurable. Therefore, $e(t)$ is replaced by the prediction
error $\epsilon(t)$

$$\epsilon(t) = y(t) - \mathbf{q}^T \hat{\mathbf{\theta}}(t - 1)$$  \hspace{1cm} (10)

where

$$\hat{\mathbf{\theta}} = [-\hat{a}_1, ..., -\hat{a}_{n_d}, \hat{b}_0, ..., \hat{b}_{n_b}, \hat{c}_1, ..., \hat{c}_{n_c}]$$  \hspace{1cm} (11)

$$\mathbf{q}^T(t) = [y(t - 1), ..., y(t - n_d), u(t - 1), ..., u(t - n_b - 1), e(t - 1), ..., e(t - n_c)]$$  \hspace{1cm} (12)

The ARMAX model structure selected in this study is
defined as:

$$y(t) = \frac{b_1 z^{-1}}{1 + \hat{a}_1 z^{-1} + \hat{a}_2 z^{-2}} u(t) + \frac{1 + \hat{c}_1 z^{-1}}{1 + \hat{a}_1 z^{-1} + \hat{a}_2 z^{-2}} \epsilon(t)$$  \hspace{1cm} (13)

C. Parameter Estimation

The recursive least squares technique allows significant
saving in the computation. Instead of recalculating the least
squares estimate in its entirety, requiring the storage of all
previous data, it merely stores the ‘old’ estimate calculated
at time $t$, denoted by $\hat{\mathbf{\theta}}(t)$, and to obtain the ‘new’ estimate
$\hat{\mathbf{\theta}}(t + 1)$ by an updating step involving the new data only.
The iterative process of recursive parameter estimation can
be visualized as shown in Fig. 1.

![Fig. 1. Iterative process of recursive parameter estimation](image)

The aim is to select a value of $\hat{\mathbf{\theta}}(t)$ so that the modeling
error is minimized according to the sum of squares of errors:

$$J = \sum_{t=1}^{\infty} \epsilon^2(t) = \mathbf{e}^T \mathbf{e}$$  \hspace{1cm} (14)

The algorithms implemented for parameters estimation of
the models under study is summarized as follows [18]:
At time step $(t + 1)$:
1) Form $\mathbf{P}(t + 1)$ using the new data $u(t + 1), y(t + 1)$ and
$e(t + 1) = y(t + 1) - \mathbf{q}^T(t + 1) \hat{\mathbf{\theta}}(t)$ .
2) Form $\mathbf{P}(t + 1)$ using $\mathbf{P}(t + 1) = \mathbf{P}(t) + \mathbf{q}(t + 1)\mathbf{P}(t + 1)\mathbf{q}^T(t + 1)$.
3) Update $\hat{\mathbf{\theta}}(t)$, $\hat{\mathbf{\theta}}(t + 1) = \hat{\mathbf{\theta}}(t) + \mathbf{P}(t + 1)\mathbf{q}(t + 1)$.

This algorithm is used to estimate the system parameters
$\hat{a}_i, \hat{b}_i, \hat{c}_i$ and $\hat{d}_i$ in Eq. (13).

D. Model Validation

The model derived in this study was validated by plotting
the output predicted by the model and comparing it with the
measured output. The quality of the identified model is
determined by the error between the measured and the
predicted value.

E. Experimental Setup

For identification purposes, a Matlab program is written
to generate the PRBS signals that fulfill the condition of
persistent. The palm oil biodiesel engine is first run at a
steady-state speed value before the input-output data were
collected. A computer is interfaced to the actuator (auto
throttle) and the speed sensor via an Agilent U2351A
Multifunction DAQ. See Fig. 2.

![Fig. 2. Block diagram of the data acquisition activities.](image)

In this experiment, a PRBS signal with maximum length
sequence of 31 with time period of 1 second and sampling
time of 0.17 second was used during data collection for
engine modeling at the speed range of around 2100 rpm.
Starting from steady-state conditions, a sequence of input
signals is injected to excite the actuator. Two sets of real-
time data were collected from the palm oil biodiesel engine
test-bed. Each set consists of 720 data. The first set was used
for model parameters estimation and identification activities
while the second set of data used for model validation. Fig.
3 shows the engine speed response during the identification
experiment when the PRBS signal was injected to the
actuator from the computer.

![Fig. 3. Input and output signals for black box identification.](image)
III. RESULTS AND DISCUSSIONS

The iterative parameter estimation algorithm used in these experiments allowed the estimation of engine model of the system to be updated at each sample interval. The estimation of the model parameters significantly depends on the choices of initial values for data vector, parameter vector and covariance matrix (P) at the first step. The experimental initial conditions designed in this study have successfully calculated the values of $a_1, a_2, b_1, c_1$ in less than 30 iterations.

Fig. 4 shows the identification process of the diesel engine. In these figures, it can be clearly seen that the model predicted outputs are closed to those of the measured engine speed values.

The convergence of the all parameters is illustrated in Fig. 5. Almost all model parameters converged to a stable value in less than ten seconds. The parameters estimated for each model structure are shown in Table III.

The predicted output of ARMAX model mentioned above is then plotted against the second set of measured data for validation purposes. From Fig. 6, it can be seen that the measured and the predicted model outputs are in very good agreement during the model validation procedure. From the observation, the model predicted values are quite accurate compared to the measured values with maximum error of 0.97%.

The modeling error between the system output (measured speed value) and the predicted model output is shown in Fig. 7. Observation on the error values show that, on average, the error values is about ±8 rpm. To further assess the adequacy of the prediction models, the estimated standard error of the regression ($\hat{\sigma}$) and the $R^2$ of the model is calculated where:

$$\hat{\sigma} = \sqrt{\frac{\text{sum of squared errors}}{\text{degree of freedom}}}$$

$$R^2 = 1 - \frac{\sum(y_i - \bar{y})^2}{\sum(y_i - \bar{y})^2}$$

The estimated ARMAX model for the palm oil biodiesel engine derived in this study is:

$$y(t) = \frac{30.6998z^{-1}}{1-1.9623z^{-1} + 0.9781z^{-2} + (1-0.1674z^{-1})z^{-1} + 0.9781z^{-2}}u(t)$$

### Table III: Comparison of Parameters for Each Model

<table>
<thead>
<tr>
<th>Model</th>
<th>$a_1$</th>
<th>$a_2$</th>
<th>$b_1$</th>
<th>$c_1$</th>
</tr>
</thead>
<tbody>
<tr>
<td>ARMAX</td>
<td>-1.9623</td>
<td>0.9781</td>
<td>30.6998</td>
<td>-0.1674</td>
</tr>
</tbody>
</table>

### Table IV: Standard Error ($\hat{\sigma}$) and $R^2$ for the Predicted Model

<table>
<thead>
<tr>
<th>Model</th>
<th>$\hat{\sigma}$</th>
<th>$R^2$</th>
</tr>
</thead>
<tbody>
<tr>
<td>ARMAX</td>
<td>5.4 rpm</td>
<td>0.94</td>
</tr>
</tbody>
</table>
Table IV shows the model fitting ARMAX model derived in this work. It can be clearly seen that the standard error of regression value is just about 6 rpm. This shows how well the fitted equation fits the sample data. Also, the value of $R^2$ which is closer to 1 indicates a goodness of fit of the estimation equation.

Thus, the dynamic mathematical model derived in this work is acceptable and valid. The model is an approximation of an automotive diesel engine fuelled with palm oil biodiesel around the speed range around 2100 rpm.

IV. CONCLUSION

In this work, the development of stochastic models of an automotive diesel engine fuel with palm oil biodiesel has been presented. The model was successfully identified using black-box modeling technique. The mathematical model developed in this paper present an analysis and simulation tools of the engine dynamic system that forms the foundation for a systematic approach to the analysis, simulation and synthesis of the automotive palm oil biodiesel engine control systems. Currently, a nonlinear model of the plant is being developed. For future work, a speed controller for this palm oil biodiesel engine will be considered.

ACKNOWLEDGEMENTS

This work was conducted in the Thermodynamic and Process Control Laboratories of School of Manufacturing Engineering, University Malaysia Perlis. The authors would like to thank the individuals who were involved in making this work possible.
